Splitting Image from Channels	7

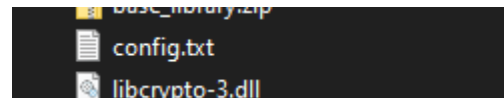

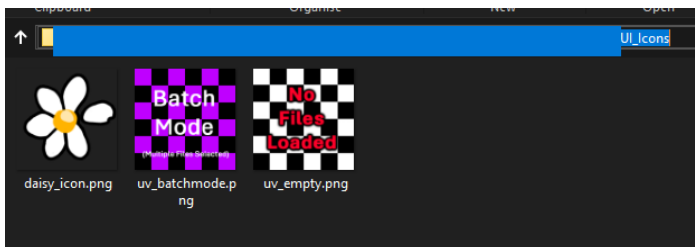

Getting Started

Tool Usage:

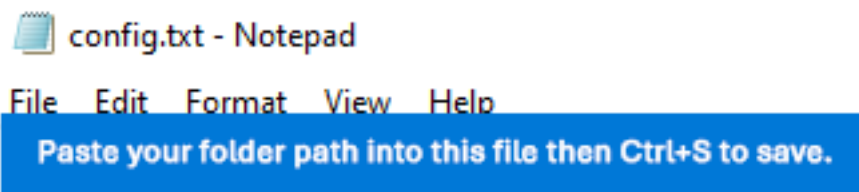

This tool is designed to help manage textures following export. Using the tabbed view you can easily change the file type, rescale, pack channels and split a image into channels. Before running, ensure you have setup your config file correctly below.

Setting Up Config:

- Go to the folder labelled UI_Icons and copy the entire path.
- Open up the _internal folder and find

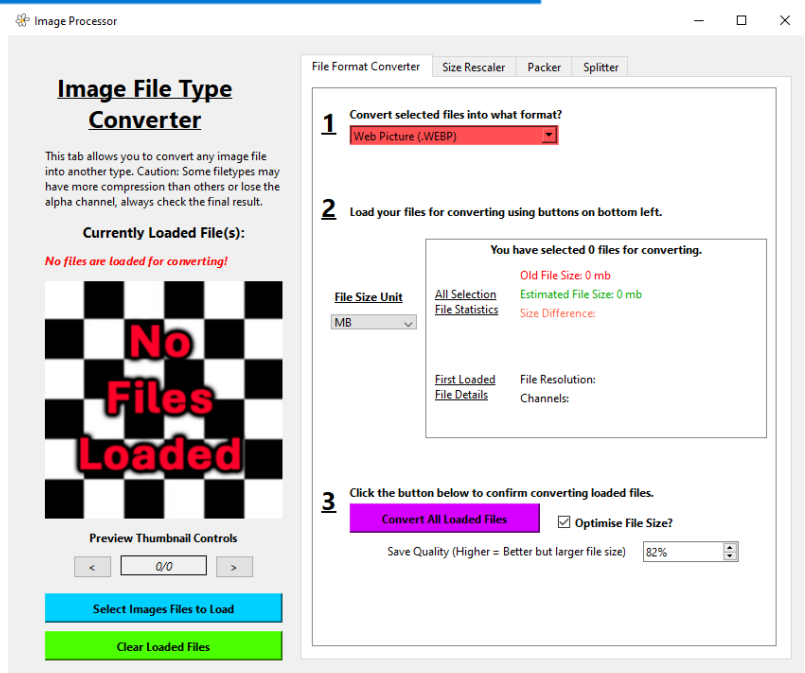

- Paste the folder path that you copied from UI_Icons into this file then save the file. If this file is missing, run the tool once and it will be created for you.

- Open the tool and you should see all icons loaded like this:

From here you can use the tool by clicking on the blue load button to input images for the tool to use.

Converting Images

Converting File Types:

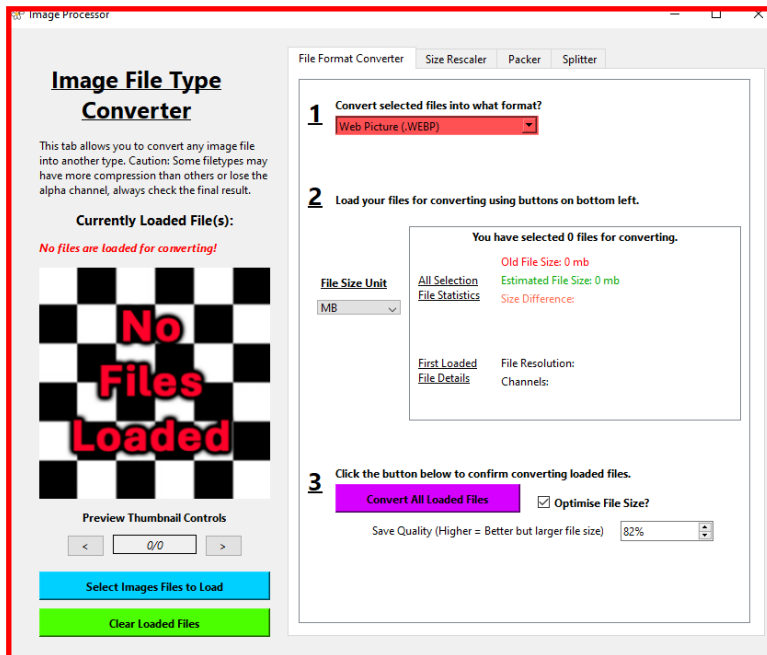

The first and default tab for the tool is for converting files. To get started click on the blue

load images icon to insert your images.

This tool supports one image at a time and batch mode (multiple images).

Once loaded the UI will update to showcase a picture of one of your images loaded in. Use the arrow buttons to check all images have loaded in.

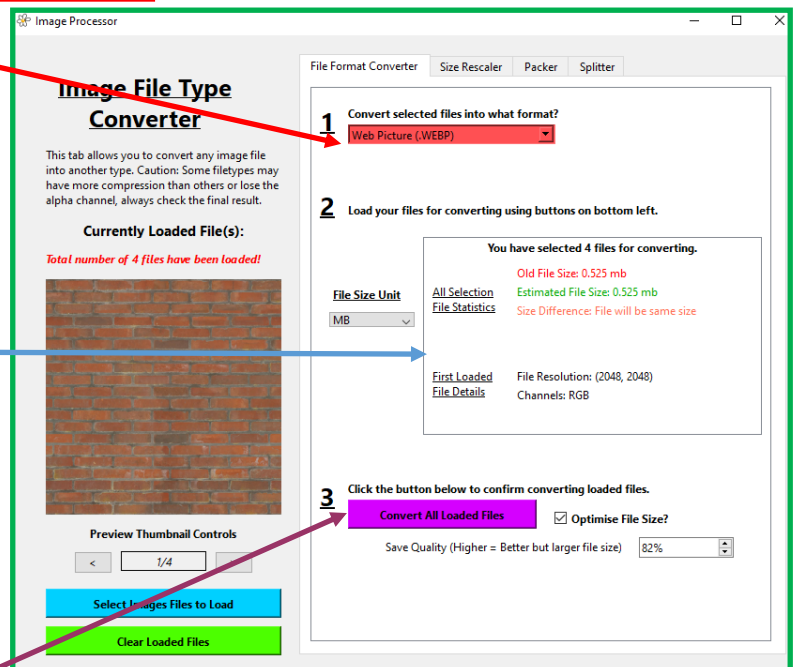

Warning: Some greyscale maps may load in more darker/lighter than they appear however this is only in the tools thumbnail viewport not on the file.

You can now select the **export file type using the red dropdown**. If the file is the same type it will ignored during export.

This box showcases useful information about the statistics of your files and the estimated file size.

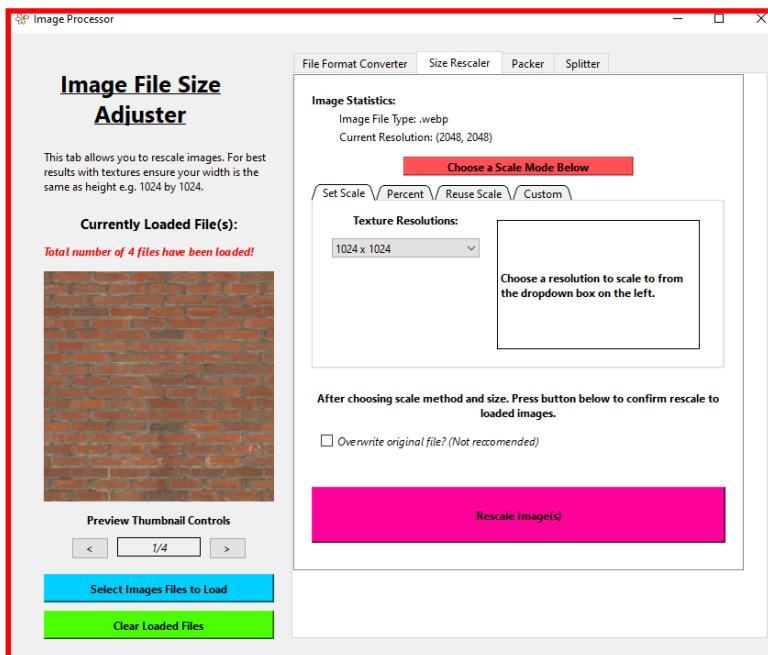

To convert your files, click on the **purple convert all loaded files button to begin.**

Tips for Smaller Texture Sizes:

By default the files will simply be optimised however if you want to **further reduce the final file size you can decrease the save quality slider and export again**. Another way to save on texture file size is to reduce resolution in the next tab.

Rescaling Images

Rescaling Images:

The second tab is for resizing your images. Ensure they are loaded with the blue load button.

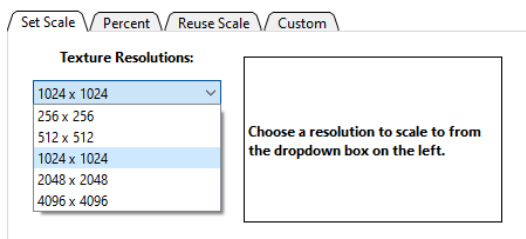

You now have 4 different options for rescaling the images:

1. Set Size Rescale
2. Percentage Reduce/Upscale
3. Reuse Scale from Thumbnail
4. Custom Resolution Input

To swap between them just use the tabs. Whichever tab is active is the one that will be chosen for export. Some advice when using these modes:

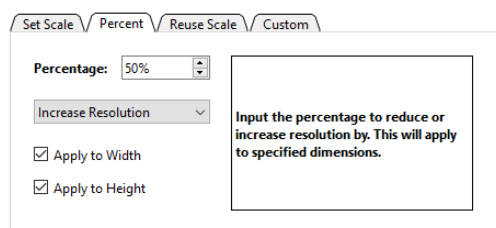

Set Scale Rescale:

When working with square texture formats this mode has a quick dropdown of the most common texture resolutions.

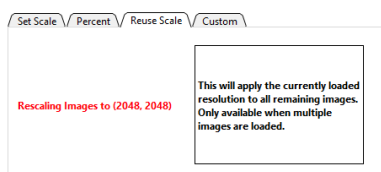

Percentage Reduce/Upscale:

This works on top of existing resolution per image, so if you want to halve all loaded images use this method.

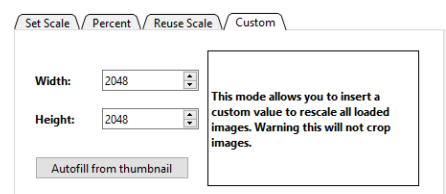

Reuse Scale from Thumbnail:

This works by setting all loaded images to match the thumbnail resolution. Good for matching tileable sizes.

Custom Resolution Input:

This option gives the most control, for quick input use the button to autofill the default values with the currently selected loaded thumbnail image.

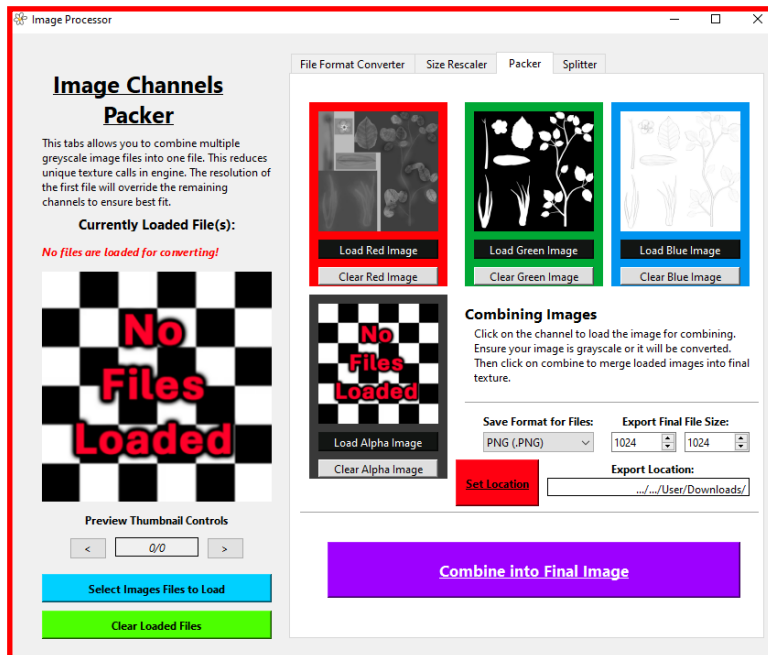

To export, click the pink button to rescale all loaded images to the chosen tab mode.

Packing Images

Packing Images to Channels:

To pack different images into one final file click on the packer tab and load your images into the selected channels.

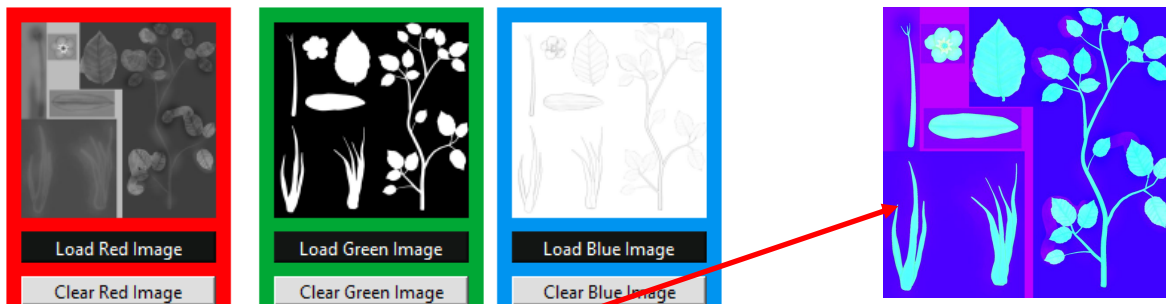

into the selected channels.

Caution: Loaded images will be converted into grayscale.

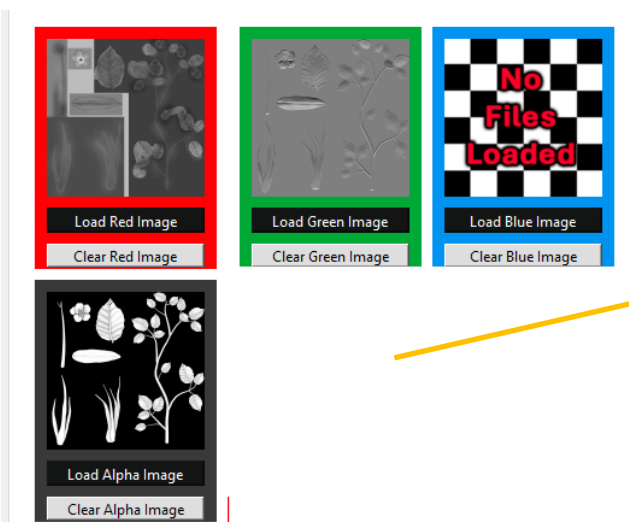

After loading all the files into the correct channels, click on **Set Location** button to set the final save location of your file.

You can also adjust the final resolution size and file format. Once setup, click on combine into final image to export.

Here are some examples of packing these files and the final result:

Packing RGB e.g AORM

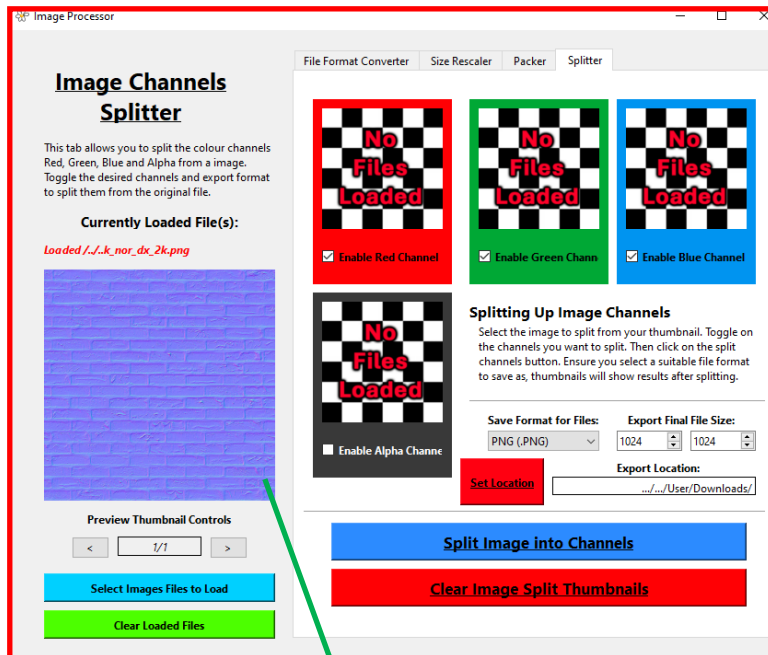

Packing RGBA to have Alpha transparency

Splitting Channels

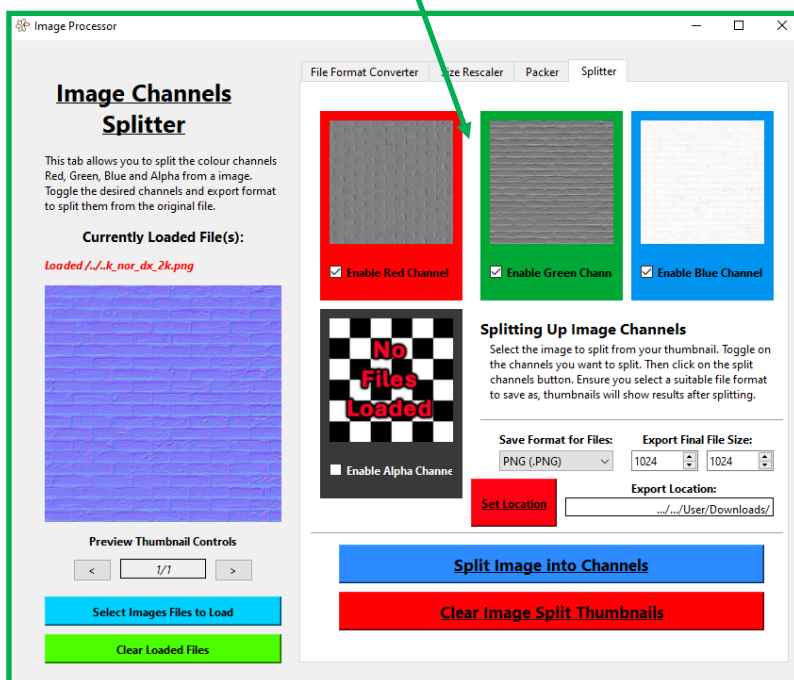

Splitting Image into Channels:

For the reverse to a colour image, **switch to the splitter tab to split a image into channels.**

Click on the **blue load images** to input a image to be split into your thumbnail. If you are working on multiple files ensure the one to split is currently previewed.

Now you can toggle all the channels you want to split to alongside the export settings, location and file type. These are synced with the packer. Once setup, click on the **darker blue split into channels button.**

One split up your channels will preview in the thumbnails alongside being exported to your folder of choice in File Explorer.

This tab works well with the combiner to split up colour channels and pack alpha into texture maps like foliage as needed.

Additionally you can quickly isolate and create masks from colour information like green for isolation leaves from trees.
